# 1 Abstract

This document presents a comprehensive modeling framework for **Loss Given Default (LGD)** estimation within the IRB (Internal Ratings-Based) approach. The work is conducted on a synthetic dataset with variables structured to resemble realistic credit portfolio data.

## Key features:

- Exploratory data analysis and LGD target construction
- Feature engineering, winsorization, and scaling
- Multiple model development: OLS, Random Forest, XGBoost
- Evaluation using  $R^2$ , RMSE, MAE, and residual plots
- Calibration analysis and downturn stress testing
- Regulatory considerations and validation recommendations

*Disclaimer:* All data and variables are simulated and do not represent any real institution or customer.

# 2 Theoretical Background

## 2.1 Definition of LGD

**Loss Given Default (LGD)** represents the portion of a credit exposure a lender expects to lose if a borrower defaults. Formally:

$$\text{LGD} = 1 - \frac{\text{Recovered Amount}}{\text{Exposure at Default (EAD)}} \quad (1)$$

LGD is expressed as a percentage or decimal between 0 and 1. A fully recovered exposure yields  $\text{LGD} = 0$ , while complete loss implies  $\text{LGD} = 1$ .

## 2.2 IRB Context and Downturn LGD

According to Basel II/III:

- LGD estimates must be **conservative** and reflect conditions during an economic downturn.
- Estimates should be based on historical recoveries and take into account *seniority*, *collateral*, and *macro conditions*.

## 2.3 Modeling LGD: Regression Perspective

In contrast to PD (a classification task), LGD modeling is formulated as a **regression problem**. The objective is to predict the continuous variable LGD using borrower and loan characteristics.

### Assumptions:

- LGD is bounded:  $0 \leq \text{LGD} \leq 1$
- Only defaulted observations (`default_flag = 1`) are used

## 3 Data Preparation

### 3.1 LGD Target Construction

$$\text{LGD}_i = 1 - \frac{\text{RecoveredAmount}_i}{\text{ExposureAtDefault}_i} \quad (2)$$

Observations with `ExposureAtDefault = 0` or  $\text{LGD} < 0$  are removed. The target is validated to ensure it lies within  $[0, 1]$ .

### 3.2 Outlier Treatment

To prevent distortion in model fitting, we apply **winsorization** at 1st and 99th percentiles:

$$X_i^{\text{winsorized}} = \begin{cases} P_1(X) & \text{if } X_i < P_1(X) \\ X_i & \text{if } P_1(X) \leq X_i \leq P_{99}(X) \\ P_{99}(X) & \text{if } X_i > P_{99}(X) \end{cases}$$

### 3.3 Feature Scaling and Transformation

Numerical features are standardized via:

$$z_i = \frac{x_i - \mu}{\sigma} \quad (3)$$

Where  $\mu$  and  $\sigma$  are the mean and standard deviation from the training set.

## 4 Modeling and Evaluation

### 4.1 Models Compared

Three models were trained using the same features:

- Linear Regression (OLS)
- Random Forest Regressor
- XGBoost Regressor

### 4.2 Evaluation Metrics

- $R^2$ : Proportion of variance explained
- **RMSE**: Root Mean Squared Error
- **MAE**: Mean Absolute Error

### 4.3 Results

Model	$R^2$	MAE	RMSE
Linear Regression	0.388	0.617	0.835
Random Forest	0.378	0.594	0.842
XGBoost	<b>0.437</b>	<b>0.575</b>	<b>0.801</b>

Table 1: LGD model performance on test data

### 4.4 Residual Analysis

Residuals ( $e_i = y_i - \hat{y}_i$ ) were plotted to assess bias and heteroskedasticity. The XGBoost model exhibited:

- Residuals centered around zero
- No clear heteroskedastic pattern
- Stable spread across predicted range

## 4.5 Calibration Assessment

We group predictions into deciles and compare:

$$\text{Calibration Error}_j = \bar{y}_j - \bar{\hat{y}}_j, \quad j = 1, \dots, 10$$

A diagonal pattern in the calibration plot confirms that predicted LGD aligns with realized losses in each bin.

## 5 Stress Testing: Downturn LGD

A downturn scenario is simulated by increasing predicted LGD by 20%:

$$\text{LGD}_{\text{stressed}} = \min(1.0, 1.2 \cdot \text{LGD}_{\text{predicted}})$$

### Result:

- Baseline mean LGD: 0.51
- Stressed mean LGD: 0.61
- Relative uplift: +19.6%

This simulates deterioration in recovery rates and aligns with Basel expectations on conservatism.

## 6 Regulatory Considerations

### 6.1 IRB Guidelines

According to CRR Article 181(1)(b):

LGD estimates must be appropriate for an economic downturn and reflect expected recoveries under adverse conditions.

### 6.2 Governance and Validation

- **Monitoring:** Track  $R^2$ , RMSE, feature drift quarterly
- **Recalibration:** Annually or after portfolio shifts
- **Audit Trail:** All modeling steps documented and reproducible

## 7 Conclusions

- XGBoost model outperforms others with  $R^2 \approx 0.44$
- Model shows good calibration and stability across test segments
- Stress testing confirms regulatory conservatism
- Documentation and preprocessing follow IRB-compliant standards

**Recommendation:** Use XGBoost for production, with linear regression retained for transparency in regulatory disclosures.
